

Normal (Gaussian) distribution

Suppose scores on an IQ test are normally distributed. If the test has a mean of 100 points and a standard deviation of 10 points, what is the probability that a person who takes the test will score between 90 and 110 points?

Solution:

We want to know the probability that the test score falls between 90 and 110. We will find the solution for this problem if we realize the following:

$$P(90 < X < 110) = P(X < 110) - P(X < 90)$$

We will compute the probability on the right side of the equation. Lets mark $P(X < 110)$ with variable **a** and $P(X < 90)$ with variable **b**.

$$P(X < 110)$$
$$a := \text{normaldist}(U, \mu, \rho)$$
$$a = 0.841$$

$$P(X < 90)$$
$$b := \text{normaldist}(V, \mu, \rho)$$
$$b = 0.159$$

$$P(90 < X < 110)$$
$$P := a - b$$
$$P = 0.683$$

About 68.3% of the test scores will fall between 90 and 110 point on IQ test.
